

# **Getting Started with TCB**

#### Introduction

Author: Marius Nicolae, Microchip Technology Inc.

The tinyAVR® 0-series, tinyAVR 1-series and megaAVR® 0-series of microcontrollers are equipped with powerful timers that enable them to cover a wide area of applications. Timer/Counter Type B (TCB) offers a variety of features and operation modes, from periodic interrupts to 8-bit PWM or time-out. The various operation modes of the TCB can be used in correlation with the event system. The scope of this technical brief is to show the configuration of three operation modes.

#### • Using TCB in 8-bit PWM mode:

TCB will be configured in this mode and will generate a PWM signal with a 50% duty cycle for a 1-second period. A GPIO pin will be used as an output to showcase the signal.

#### Using TCB in Time-Out Check mode:

TCB will be configured in this mode and will be used to measure the signal time (edge-to-edge) generated by a GPIO pin configured as input. An interrupt will be generated if the time-out (period from edge-to-edge) expires.

#### · Using TCB in Sleep mode:

TCB will be configured to generate a periodic interrupt, even when the  $\mathsf{AVR}^{@}$  microcontroller is in Standby Sleep mode.

**Note:** In each example, GPIOs are used either for input (event system input signal), or for output (e.g. toggling a pin each time an interrupt occurs). The code examples were developed using the ATmega4809 Xplained Pro (ATMEGA4809-XPRO) development board, but are suitable for the entire tinyAVR 0-series, tinyAVR 1-series and megaAVR 0-series.

### 1. Relevant Devices

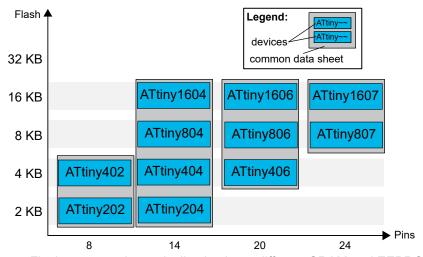

This chapter lists the relevant devices for this document.

# 1.1 tinyAVR® 0-series

The figure below shows the tinyAVR 0-series, laying out pin count variants and memory sizes:

- Vertical migration is possible without code modification, as these devices are fully pin- and feature compatible.
- · Horizontal migration to the left reduces the pin count and, therefore, the available features.

Figure 1-1. tinyAVR® 0-series Overview

Devices with different Flash memory size typically also have different SRAM and EEPROM.

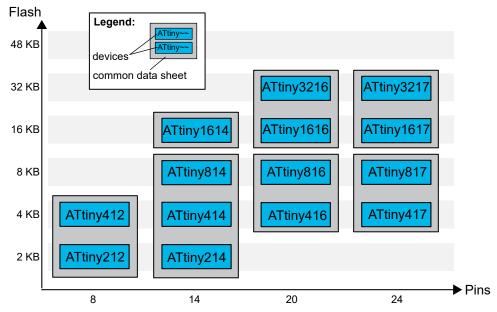

# 1.2 tinyAVR® 1-series

The following figure shows the tinyAVR 1-series devices, laying out pin count variants and memory sizes:

- Vertical migration upwards is possible without code modification, as these devices are pin compatible and provide the same or more features. Downward migration may require code modification due to fewer available instances of some peripherals.
- Horizontal migration to the left reduces the pin count and, therefore, the available features.

**Relevant Devices** 

Figure 1-2. tinyAVR® 1-series Overview

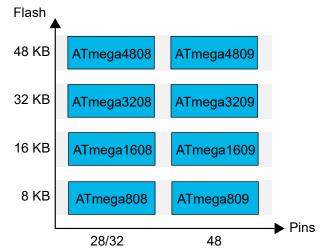

Devices with different Flash memory size typically also have different SRAM and EEPROM.

# 1.3 megaAVR® 0-series

The figure below shows the megaAVR 0-series devices, laying out pin count variants and memory sizes:

- Vertical migration is possible without code modification, as these devices are fully pin and feature compatible.
- Horizontal migration to the left reduces the pin count and, therefore, the available features.

Figure 1-3. megaAVR® 0-series Overview

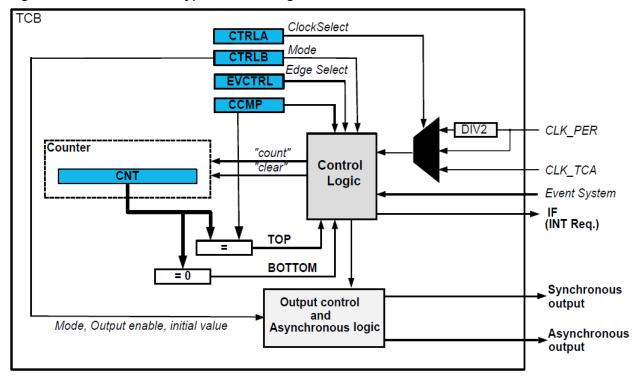

Devices with different Flash memory size typically also have different SRAM and EEPROM.

### 2. Overview

The capabilities of the 16-bit Timer/Counter type B (TCB) include frequency, waveform generation, and input capture on an event with time and frequency measurement of the digital signals. The TCB consists of a base counter and a control logic that can be set in one of the eight different modes, each mode providing unique functionality. The base counter is clocked by the peripheral clock with optional prescaling, as shown below.

Figure 2-1. Timer/Counter Type-B Block Diagram

### 3. Using TCB in 8-bit PWM mode

**Use case description**: TCB (the TCB3 instance) will be configured in 8-bit PWM mode and generate a 1-second period PWM signal, at a 50% duty cycle. A GPIO pin (Port B pin 5 - PB5) will be used as an output to showcase the signal.

**Result**: TCB will generate a 50% duty cycle PWM signal for a 1-second period. The on-board LED (the PB5 pin) will toggle every 500 ms.

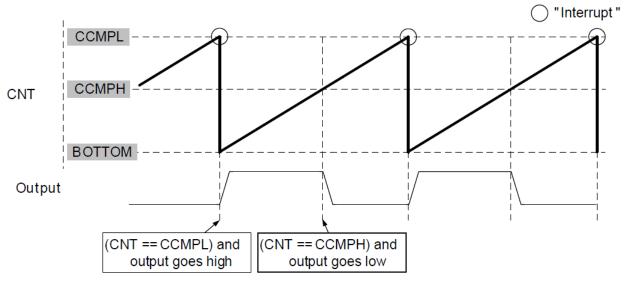

This timer can be configured to run in 8-bit PWM mode where each of the register pairs in the 16-bit Capture/Compare register (TCBn.CCMPH and TCBn.CCMPL) is used as an individual compare register. The counter will continuously count from zero to CCMPL and the output will be set at BOTTOM and cleared when the counter reaches CCMPH.

When this peripheral is in PWM mode and enabled, changing the value of the Capture/Compare register will change the output, but the transition may render invalid values. It is hence recommended to:

- 1. Disable the peripheral.
- 2. Write Capture/Compare register to {CCMPH, CCMPL}.
- 3. Write 0x0000 to count register.
- 4. Re-enable the module.

CCMPH is the number of cycles for which the output will be driven high, while CCMPL+1 is the period of the output pulse.

Figure 3-1. 8-Bit PWM Mode

For example, for a 256 Hz frequency clock that serves as input to the timer, the result is a 1-second period (CCMPL is an 8-bit register, which means it can have values from 0 to 255).

#### Configuring a pin as output for visualizing the PWM signal

To visualize the PWM, a pin will be configured in the Output mode. The following code sets PB5 as output low.

```
PORTB_OUT |= PIN5_bm;
PORTB_OUT |= PIN5_bm;
```

#### Configuring the system clock

According to the diagram in Figure 2-1, there are two main clock sources for TCB:

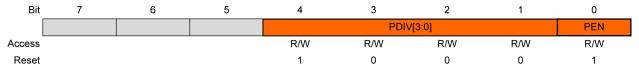

- CLK\_PER (the peripheral clock, derived from main clock CLK\_MAIN)
- CLK\_TCA (the TCA clock, which can be derived from CLK\_PER)

For the purpose of this use case of TCB, CLK\_PER clock source and instance 3 of TCB will be used (TCB3). In order to get a 1-second period, the input clock must be as low as possible. The following configuration must be made:

- Internal 32 kHz ultra low-power oscillator for CLKSEL must be selected
- · The clock prescaler (PEN) must be enabled
- The highest prescaler division (PDIV 64) must be used

In order to use the 32 kHz internal oscillator as clock source for TCB, the user must configure the following registers and bits or bit fields in the following register.

Figure 3-2. MCLKCTRLB Register Configuration

#### bits 4:1PDIV[3:0]: Prescaler Division bits

If the Prescaler Enable (PEN) bit is written to '1', these bits define the division ratio of the main clock prescaler.

| Value | Description |
|-------|-------------|
| Value | Division    |
| 0x5   | 64          |

#### bit 0 PEN: Prescaler Enable bit

This bit must be written '1' to enable the prescaler. When enabled, the division ratio is selected by the PDIV bit field.

The Main Clock and Prescaler Configuration registers (CLKCTRL.MCLKCTRLA,

CLKCTRL.MCLKCTRLB) are protected by the Configuration Change Protection (CCP) mechanism, employing a timed-write procedure for changing these registers. In order to write to these registers, a certain key must be written to the CPU.CCP register first, followed by a write access to the protected bits within four CPU instructions.

The key that must be written to the CPU.CPP register is 'IOREG', which translates into the line of code from below. For more details, check Configuration Change Protection (CCP) in the megaAVR 0-series family data sheet.

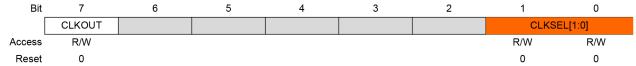

**Note:** The CPU\_CPP register will allow only one READ/WRITE instruction and the change must be made in the following four cycles, after writing the key.

CPU CCP = CCP IOREG gc;

Since the desired frequency is the lowest possible, the Prescaler (PEN) must be enabled and PDIV must be set to '64' divider.

```
CLKCTRL.MCLKCTRLB = CLKCTRL_PDIV_64X_gc | CLKCTRL_PEN_bm;
```

#### Figure 3-3. MCLKCTRLA Register Configuration

#### bits 1:0 CLKSEL[1:0]: Clock Select bits

This bit field selects the source for the Main Clock (CLK\_MAIN).

| Value | Name      | Description                                |
|-------|-----------|--|
| 0x0   | OSC20M    | 20 MHz internal oscillator                 |
| 0x1   | OSCULP32K | 32 KHz internal ultra low-power oscillator |
| 0x2   | XOSC32K   | 32.768 kHz external crystal oscillator     |
| 0x3   | EXTCLK    | External clock                             |

OSCULP32K must be selected, which means CLKSEL bit field must be set to 0x1 value. This translates into the following code:

```
CLKCTRL.MCLKCTRLA = CLKCTRL_CLKSEL_OSCULP32K_gc;
```

#### Figure 3-4. MCLKSTATUS Register Configuration

| Bit    | 7    | 6        | 5       | 4       | 3 | 2 | 1 | 0    |
|--------|------|----------|---------|---------|---|---|---|------|
|        | EXTS | XOSC32KS | OSC32KS | OSC20MS |   |   |   | SOSC |
| Access | R    | R        | R       | R       |   |   |   | R    |
| Reset  | 0    | 0        | 0       | 0       |   |   |   | 0    |

#### bit 0 SOSC: Main Clock Oscillator Changing bit

| Value | Description  |
|-------|--|
| 0     | The clock source for CLK_MAIN is not undergoing a switch   |
| 1     | The clock source for CLK_MAIN is undergoing a switch and will change as soon as the new source is stable |

The clock switching process is indicated by the SOSC bit. The program should halt during an undergoing switch of the clock source, so a wait until the switch is over should be implemented:

```
while (CLKCTRL.MCLKSTATUS & CLKCTRL_SOSC_bm)
{
   ;
}
```

#### Configuring the TCB input clock and operation mode

In order to generate the 8-bit PWM signal to PB5, the following registers must be changed:

- TCBn.CCMP
- TCBn.CTRLA
- TCBn.CTRLB

The TCBn.CCMPL and TCBn.CCMPH register pair represents the 16-bit value TCBn.CCMP. The low byte <7:0> (suffix L) is accessible at the original offset. The high byte <15:8> (suffix H) can be accessed at offset +0x01. In 8-bit PWM mode, TCBn.CCMPL and TCBn.CCMPH act as two independent registers.

Figure 3-5. TCBn.CCMP Register Configuration

| Bit    | 15         | 14  | 13  | 12  | 11     | 10  | 9   | 8   |  |
|--------|------------|-----|-----|-----|--------|-----|-----|-----|--|
|        | CCMP[15:8] |     |     |     |        |     |     |     |  |
| Access | R/W        | R/W | R/W | R/W | R/W    | R/W | R/W | R/W |  |
| Reset  | 0          | 0   | 0   | 0   | 0      | 0   | 0   | 0   |  |
|        |            |     |     |     |        |     |     |     |  |
| Bit    | 7          | 6   | 5   | 4   | 3      | 2   | 1   | 0   |  |
|        |            |     |     | CCM | P[7:0] |     |     |     |  |
| Access | R/W        | R/W | R/W | R/W | R/W    | R/W | R/W | R/W |  |
| Reset  | 0          | 0   | 0   | 0   | 0      | 0   | 0   | 0   |  |

bits 15:8 CCMP[15:8]: Capture/Compare Value High Byte

These bits hold the MSB of the 16-bit compare, capture, and top value.

bits 7:0 CCMP[7:0]: Capture/Compare Value Low Byte

These bits hold the LSB of the 16-bit compare, capture, and top value.

When running TCB in 8-bit PWM mode, TCBn.CCMPL must be loaded with the PWM signal period, of 1 second in this case. Since the period of the output pulse is defined by TCBn.CCMPL+1, the value that must be loaded into the TCBn.CCMPL register is 0xFF (255 in decimal).

Subsequently, TCBn.CCMPH must be loaded with the number of cycles for which the output will be driven high. The goal is to set the duty cycle at 50% in order to make PB5 toggle every 500 ms.

$$CCMPH = \left(CCMPL + 1\right) \times \frac{50}{100}$$

CCMPH = 128

This results in TCBn.CCMPH=128=0x80

This means that TCBn.CCMP must be loaded with the following value, obtained from TCBn.CCMPH and TCBn.CCMPL:

TCB3.CCMP = 0x80FF;

| Figure 3-6. TCBn.CTRLA Register Configuration |           |     |     |      |         |     |     |     |  |
|---|-----------|-----|-----|------|---------|-----|-----|-----|--|
| Bit   | 15        | 14  | 13  | 12   | 11      | 10  | 9   | 8   |  |
|   |           |     |     | CCMF | P[15:8] |     |     |     |  |
| Access  | R/W       | R/W | R/W | R/W  | R/W     | R/W | R/W | R/W |  |
| Reset   | 0         | 0   | 0   | 0    | 0       | 0   | 0   | 0   |  |
| Bit   | 7         | 6   | 5   | 4    | 3       | 2   | 1   | 0   |  |
|   | CCMP[7:0] |     |     |      |         |     |     |     |  |
| Access  | R/W       | R/W | R/W | R/W  | R/W     | R/W | R/W | R/W |  |
| Reset   | 0         | 0   | 0   | 0    | 0       | 0   | 0   | 0   |  |

bits 15:8 CCMP[15:8]: Capture/Compare Value High Byte

These bits hold the MSB of the 16-bit compare, capture, and top value.

bits 7:0 CCMP[7:0]: Capture/Compare Value Low Byte

These bits hold the LSB of the 16-bit compare, capture, and top value.

TCB3 can be enabled by setting the ENABLE bit to '1' in the TCB3.CTRLA register. This translates into the following code:

TCB3.CTRLA |= TCB ENABLE bm;

In order to get the lowest possible frequency, CLK\_PER will be further divided by 2, by configuring the CLKSEL bit field in the TCB3.CTRLA register. The corresponding value for CLKSEL in this case is 0x1. This translates into the following code:

TCB3.CTRLA |= TCB\_CLKSEL\_CLKDIV2\_gc;

#### Figure 3-7. TCBn.CTRLB Register Description

| Bit    | 7 | 6     | 5        | 4      | 3 | 2   | 1            | 0   |
|--------|---|-------|----------|--------|---|-----|--------------|-----|
|        |   | ASYNC | CCMPINIT | CCMPEN |   |     | CNTMODE[2:0] |     |
| Access |   | R/W   | R/W      | R/W    |   | R/W | R/W          | R/W |
| Reset  |   | 0     | 0        | 0      |   | 0   | 0            | 0   |

#### bit 4 CCMPEN: Compare/Capture Output Enable bit

This bit is used to enable the output signal of the Compare/Capture.

| Value | Description                              |
|-------|--|
| 0     | Compare/Capture Output is zero           |
| 1     | Compare/Capture Output has a valid value |

#### bits 2:0 CNTMODE[2:0]: Timer Mode bits

Writing these bits selects the Timer mode.

| Value | Description             |
|-------|-------------------------|
| 0x0   | Periodic Interrupt mode |
| 0x1   | Time-out Check mode     |
| 0x7   | 8-Bit PWM mode          |

#### CCMPEN must be enabled. This translates into the following code:

TCB3.CTRLB |= TCB\_CCMPEN\_bm;

TCB must be configured for the 8-bit PWM mode. This translates to the following code:

TCB3.CTRLB |= TCB\_CNTMODE\_PWM8\_gc;

**Tip:** The full code example is also available in the Appendix section.

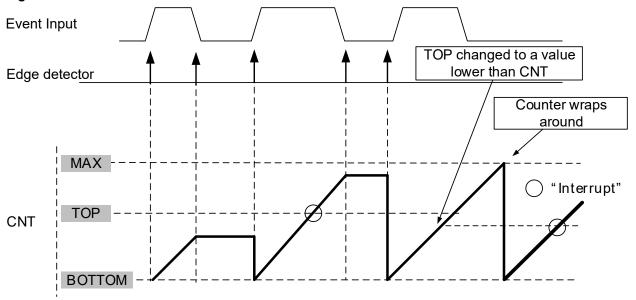

### 4. Using TCB in Time-Out Check Mode

**Use case description**: Configure TCB in Time-out Check mode and measure the signal time generated by a GPIO (configured as input). The time-out will be set to two seconds and the event system will be used to detect the rising edge and falling edge of the signal generated by a GPIO (e.g. a push button in a real application). If the time-out expires, another GPIO (e.g. an LED, in a real application) will be toggled in the interrupt.

**Result**: Use a GPIO as input to generate an event that serves as input signal for TCB. Generate an interrupt when the time-out expires.

In the Time-out Check mode, TCB relies on the interaction with the event system, as displayed in the figure below. In this mode, the counter counts to MAX and wraps around. On the first edge, the counter is restarted and on the second edge, the counter is stopped. If the count register (TCBn.CNT) reaches TOP before the second edge, an interrupt will be generated. In Freeze state, the counter will restart on a new edge. Reading count (TCBn.CNT) or the Capture/Compare (TCBn.CCMP) register, or writing the RUN bit (RUN in TCBn.STATUS) in Freeze state will have no effect.

Figure 4-1. Time-out Check Mode

#### Configuring the system clock

In order to obtain a 2-second period for the 16-bit TCB timer, the input frequency must be as low as possible. For this, the internal 32 kHz oscillator can be used. There is no need to use a frequency divider, so the prescaler for CLK\_PER must be disabled. There are three steps in the configuration process:

 Disable the CLK\_PER prescaler - The following code snippet will demonstrate how to disable the CLK\_PER prescaler.

```
CPU_CCP = CCP_IOREG_gc;
CLKCTRL.MCLKCTRLB = 0 << CLKCTRL_PEN_bp;</pre>
```

2. **Select the internal 32 kHz oscillator** - The following code snippet will switch the system clock source to the internal 32 kHz oscillator.

```
CPU_CCP = CCP_IOREG_gc;
CLKCTRL.MCLKCTRLA = CLKCTRL_CLKSEL_OSCULP32K_gc;
```

3. **Wait for the clock switch process to complete** - The following code snippet will demonstrate how to wait for the clock source switching process to finish.

```
while (CLKCTRL.MCLKSTATUS & CLKCTRL_SOSC_bm)
{
   ;
}
```

#### Note:

- 1. Writing to the MCLKCTRLA and MCLKCTRLB registers requires the 'IOREG' key to be written to the CPU.CCP register, prior to accessing the clock control registers.
- The clock control registers are described in 'Using TCB in 8-bit PWM mode' chapter of this document.

#### **Configuring TCB in Time-out Check Mode**

In order to generate a signal using a GPIO pin, event system must be set up accordingly. Port B Pin 2 (PB2) will be used as an example in this document.

The following registers must be configured:

- TCB0.CCMP
- TCBn.INTCTRL
- TCBn.EVCTRL
- EVSYS.CHANNEL
- EVSYS.USER

#### 1. TCB0.CCMP Configuration

The TCB Compare/Capture register must be loaded with the value of the time-out. For the purpose of this document, a value of one second for the time-out has been chosen. With an input frequency of 32.768 Hz, the 16-bit counter will make a complete cycle in two seconds (the maximum value of a 16-bit number is 65535).

The reload value of TCB0.CCMP can be calculated, as shown below:

$$CCMP = \frac{CNT \text{ max}}{2}$$

$$CCMP = \frac{65535}{2}$$

$$CCMP = 32767.5$$

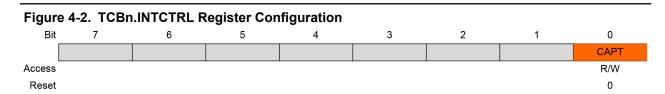

A value of 32767.5 cannot be translated into hex, so 32767 will be used instead.

```
CCMP = 32767.5 = \sim 32767 = 0 \times 7FFF
```

The following code snippet will load TCB0.CCMP with 0x7FFF time-out value.

```
TCB0.CCMP = 0x7fff;
```

### 2. TCBn.INTCTRL Configuration

bit 0 CAPT: Capture Interrupt Enable bit

Writing this bit to '1' enables the Capture interrupt.

TCB0.CNT will start increasing as soon as a signal edge is detected on the event system bus. If the complementary edge of the signal is not detected within the time-out, TCB0 will trigger an interrupt. In this regard, capture or time-out interrupt must be enabled in the TCB0.INCTRL register. The following code snippet enables the interrupt:

```
TCBO.INTCTRL = TCB CAPT bm;
```

**Note:** The global interrupts must also be enabled. This can be done at a later step in the software program.

#### 3. TCBn.EVCTRL Configuration

Figure 4-3. TCBn.EVCTRL Register Configuration

| Bit    | 7 | 6      | 5 | 4    | 3 | 2 | 1 | 0      |  |
|--------|---|--------|---|------|---|---|---|--------|--|
|        |   | FILTER |   | EDGE |   |   |   | CAPTEI |  |
| Access |   | R/W    |   | R/W  |   |   |   | R/W    |  |
| Reset  |   | 0      |   | 0    |   |   |   | 0      |  |

#### bit 4 EDGE: Event Edge bit

This bit is used to select the event edge. The effect of this bit is dependent on the selected Count Mode (CNTMODE) in TCBn.CTRLB. "-" means that an event or edge has no effect in this mode.

| Count Mode         | EDGE | Positive Edge | Negative Edge |
|--------------------|------|---------------|---------------|
| Timeout Check mode | 0    | Start counter | Stop counter  |
|                    | 1    | Stop counter  | Start counter |

#### bit 0 CAPTEI: Capture Event Input Enable bits

Writing this bit to '1' enables the input capture event.

The target is to measure the signal time between the falling edge and the rising edge of the PB2 input pin (in Idle, the pin is kept in high state). This means both CAPTEI and EDGE bits must be set to '1'. The following code snippet enables both bits in the TCB0.EVCTRL register.

```
TCBO.EVCTRL = TCB CAPTEI bm | TCB EDGE bm;
```

#### 4. EVSYS.CHANNEL Configuration

Each channel can be connected to a one-event generator. Not all generators can be connected to all channels. Refer to the table below to see which generator sources can be routed onto each channel, and the generator value that must be written to EVSYS.CHANNELn to achieve this routing. The value 0x00 in EVSYS.CHANNELn turns the channel off.

#### Figure 4-4. EVSYS.CHANNEL Register Configuration

| Bit    | 7   | 6   | 5   | 4      | 3        | 2   | 1   | 0   |
|--------|-----|-----|-----|--------|----------|-----|-----|-----|
|        |     |     |     | GENERA | TOR[7:0] |     |     |     |
| Access | R/W | R/W | R/W | R/W    | R/W      | R/W | R/W | R/W |
| Reset  | 0   | 0   | 0   | 0      | 0        | 0   | 0   | 0   |

bits 7:0 GENERATOR[7:0]: Channel Generator Selection bits

| GENERATO  | ₹         | INPUT      | Async/Sync | СН0   | CH1   | CH2  | СНЗ    | CH4  | CH5    | CH6 | CH7 |
|-----------|-----------|------------|------------|-------|-------|------|--------|------|--------|-----|-----|
| binary    | hex       |            |            |       |       |      |        |      |        |     |     |
| 0100_0nnn | 0x40-0x47 | PORT0_PINn | Async      | PORTA | _PINn | PORT | C_PINn | PORT | E_PINn |     |     |
| 0100_1nnn | 0x48-0x4F | PORT1_PINn | Async      | PORTE | PINn  | PORT | D_PINn | PORT | F_PINn |     |     |

EVSYS.CHANNEL must be loaded with 0x4A value for PB2 to generate an input event, as represented in the following code snippet:

EVSYS.CHANNEL0 = EVSYS\_GENERATOR\_PORT1\_PIN2\_gc;

#### 5. EVSYS.USER Configuration

Each event user can be connected to one channel. Several users can be connected to the same channel. The following table lists all event system users, with their corresponding user ID number. This ID number corresponds to the USER register index, e.g. the user with ID 2 is controlled by the EVSYS.USER2 register.

Figure 4-5. EVSYS.USERTCB0 Register Configuration

| USER# | User Name | Async/Sync | Description   |
|-------|-----------|------------|---------------|
| 20    | ТСВ0      | Async      | TCB0 Event in |

| Bit    | 7   | 6   | 5   | 4     | 3        | 2   | 1   | 0   |
|--------|-----|-----|-----|-------|----------|-----|-----|-----|
|        |     |     |     | CHANN | IEL[7:0] |     |     |     |
| Access | R/W | R/W | R/W | R/W   | R/W      | R/W | R/W | R/W |
| Reset  | 0   | 0   | 0   | 0     | 0        | 0   | 0   | 0   |

bits 7:0 CHANNEL[7:0]: User Channel Selection bits

Describes which event system channel the user is connected to.

| Value | Description  |
|-------|--|
| 0     | OFF, no channel is connected to this event system user |
| n     | Event user is connected to CHANNEL(n-1)                |

The user channel must be linked to the event channel already configured previously (in EVSYS.CHANNEL). The following code snippet illustrates how this can be done:

EVSYS.USERTCB0 = EVSYS CHANNEL CHANNELO gc;

**Tip:** The full code example is also available in the Appendix section.

### 5. Using TCB in Sleep Mode

**Use case description**: Configure TCB to generate an overflow interrupt every second, even when the microcontroller is in Standby Sleep mode and toggle a GPIO pin (PB5).

**Result**: TCB overflow interrupt will be triggered every one second, regardless of the running mode of the microcontroller (Idle/Standby). In the Interrupt Service Routine (ISR), the on-board LED, corresponding to PB5, will be toggled..

TCBn is by default disabled in Standby Sleep mode; as soon as the microcontroller enters Sleep mode, TCB will be halted. The module can stay fully operational in Standby Sleep mode if the Run In Standby (RUNSTDBY) bit in the TCBn.CTRLA register is written to '1'.

#### Configuring the System Clock for Sleep Mode

In order to obtain a 1-second interrupt for the 16-bit TCB timer, the input frequency must be as low as possible. For this, the internal 32 kHz oscillator can be used. There is no need to use a frequency divider, so the prescaler for CLK\_PER must be disabled. There are three steps in the configuration process:

1. **Disable the CLK\_PER prescaler** - The following code snippet will demonstrate how to disable the CLK\_PER prescaler:

```
CPU_CCP = CCP_IOREG_gc;
CLKCTRL.MCLKCTRLB = 0 << CLKCTRL_PEN_bp;</pre>
```

2. **Select the internal 32 kHz oscillator** - The following code snippet will switch the system clock source to the internal 32 kHz oscillator.

```
CPU_CCP = CCP_IOREG_gc;
CLKCTRL.MCLKCTRLA = CLKCTRL_CLKSEL_OSCULP32K_gc;
```

Wait for the clock switch process to complete - The following code snippet will demonstrate how
to wait for the clock source switching process to finish.

```
while (CLKCTRL.MCLKSTATUS & CLKCTRL_SOSC_bm)
{
   ;
}
```

#### **Configuring the Sleep Mode Operation**

Sleep modes are used to shut down peripherals and clock domains in the device in order to save power. The Sleep Controller (SLPCTRL) controls and handles the transitions between Active and Sleep mode. Four modes are available: one Active mode in which software is executed, and three Sleep modes. The available Sleep modes are: Idle, Standby, and Power-Down mode.

The interrupts are used to wake the device from Sleep. The available interrupt wake-up sources depend on the configured Sleep mode. When an interrupt occurs, the device will wake up and execute the interrupt service routine before continuing normal program execution from the first instruction following the SLEEP instruction.

| Figure 5-1. SLPCTRL.CTRLA Register |   |   |   |   |   |      |        |     |  |  |
|------------------------------------|---|---|---|---|---|------|--------|-----|--|--|
| Bit                                | 7 | 6 | 5 | 4 | 3 | 2    | 1      | 0   |  |  |
|                                    |   |   |   |   |   | SMOE | E[1:0] | SEN |  |  |
| Access                             | R | R | R | R | R | R/W  | R/W    | R/W |  |  |
| Reset                              | 0 | 0 | 0 | 0 | 0 | 0    | 0      | 0   |  |  |

#### bits 2:1 SMODE[1:0]: Sleep Mode bits

Writing these bits selects the sleep mode entered when the Sleep Enable bit (SEN) is written to '1' and the SLEEP instruction is executed.

| Value | Name    | Description                   |
|-------|---------|-------------------------------|
| 0x0   | IDLE    | Idle Sleep mode enabled       |
| 0x1   | STANDBY | Standby Sleep mode enabled    |
| 0x2   | PDOWN   | Power-Down Sleep mode enabled |
| other | -       | Reserved                      |

#### bit 0 SEN: Sleep Enable bit

This bit must be written to '1' before the SLEEP instruction is executed to make the MCU enter the selected Sleep mode.

The TCB module can run while the microcontroller is in Standby Sleep mode. The Power-Down Sleep mode disables TCB completely.

For the purpose of this use case, the ATmega4809 microcontroller will be configured to enter Sleep in Standby Sleep mode. Entering Sleep must also be enabled. The following code enables the Sleep operation and configures the ATmega4809 microcontroller to enter Standby Sleep mode when SLEEP instruction is executed.

SLPCTRL.CTRLA = SLPCTRL SMODE gm | SLPCTRL SMODE STDBY gc;

#### **Configuring TCB in Periodic Interrupt Mode**

The following configuration must be made to the registers:

- TCBn.CCMP
- TCBn.CTRLA

The TCB Capture/Compare register must be loaded with a comparison value which will trigger an interrupt. For the purpose of this document, a value of one second for the periodic interrupt has been chosen. With an input frequency of 32.768 Hz, the 16-bit counter will make a complete cycle in two seconds (the maximum value of a 16-bit number is 65.535). Since the maximum value the 16-bit TCB counter can achieve its 65.535 for the 2-second maximum period, the CCMP register must be loaded with half of the maximum value – 32.768 (0x7FFF). The following code snippet loads the TCB0.CCMP register with 0x7FFF:

TCB0.CCMP = 0x7fff;

#### Figure 5-2. TCBn.CTRLA Register Configuration

| Bit    | 7 | 6        | 5 | 4       | 3 | 2     | 1       | 0      |
|--------|---|----------|---|---------|---|-------|---------|--------|
|        |   | RUNSTDBY |   | SYNCUPD |   | CLKSI | EL[1:0] | ENABLE |
| Access |   | R/W      |   | R/W     |   | R/W   | R/W     | R/W    |
| Reset  |   | 0        |   | 0       |   | 0     | 0       | 0      |

#### bit 6 RUNSTDBY: Run in Standby bit

Writing a '1' to this bit will enable the peripheral to run in Standby Sleep mode. Not applicable when CLKSEL is set to 0x2 (CLK TCA).

Prescaling is not needed, so the divider value will be '0'. Also, the timer must be enabled. In order for the TCB to still generate an interrupt while in Standby Sleep mode, the RUNSTDBY bit must also be enabled. The following code snippet sets the clock divider to '0' (no prescaling), enables the timer and allows the timer to run in Standby Sleep mode:

```
TCB0.CTRLA = TCB_CLKSEL_CLKDIV1_gc | TCB_ENABLE_bm | TCB_RUNSTDBY_bm;
```

In order to trigger a periodic interrupt, the CAPT bit of the TCB0.INTCTRL register must be enabled. The following code snippet enables the interrupt:

```
TCB0.INTCTRL = TCB_CAPT_bm;
```

#### Note:

- The global interrupts must be also enabled. This can be done at a later step in the software program.
- 2. All operations are halted in Power-Down Sleep mode.

#### Configuring a pin as output for visualizing interrupt occurrence

To visualize the periodic interrupt occurrence, the PB5 pin will be configured in output mode. The following code sets PB5 as output low.

```
PORTB_DIR |= PIN5_bm;
PORTB_OUT |= PIN5_bm;
```

**Tip:** The full code example is also available in the Appendix section.

### The Microchip Web Site

Microchip provides online support via our web site at <a href="http://www.microchip.com/">http://www.microchip.com/</a>. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- Product Support Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- General Technical Support Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- Business of Microchip Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

### **Customer Change Notification Service**

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at <a href="http://www.microchip.com/">http://www.microchip.com/</a>. Under "Support", click on "Customer Change Notification" and follow the registration instructions.

### **Customer Support**

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- · Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: http://www.microchip.com/support

# Microchip Devices Code Protection Feature

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of
  these methods, to our knowledge, require using the Microchip products in a manner outside the
  operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is
  engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.

 Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

# **Quality Management System Certified by DNV**

#### ISO/TS 16949

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
